SFDC Build Tool

Describe a Salesforce need in plain language. Review it. Deploy it, or take the package with you.

Try it: salesforce-debugtool.herokuapp.com/flow-tool

Build: create Flows, Apex, LWCs, objects, fields, prompt templates and agents from one request. The model never writes raw metadata XML: it drafts a validated design, and the diagram you approve and the XML that deploys come from that same source, so they cannot disagree.

Where the AI is: the LLM understands the request, splits it into pieces, drafts each design, explains it, and applies your changes. Everything that must be exactly right (validation, XML, approval, deploy) is deterministic code, or you.

WITHOUT VS. WITH AN ORG CONNECTION

Not connected (design only)

- Generate and refine Flows, Apex, LWC, objects, fields, AI prompts, agents, in one plan
- Diagram, plain-English explanation, generated code, test guide
- Download the report and a ready Metadata API package (.zip); deploy it yourself with sf CLI / Workbench
- Share a review link with a colleague

Never contacts a Salesforce org.

Connected to an org

- Everything on the left, plus:
- **Browse and open existing** Flows, Apex, triggers, LWCs, objects, fields, prompts; ask what they do, change them
- **Validate** against the real org (check-only, nothing created)
- **Deploy** in one transaction, with a link into Flow Builder
- Org errors go back to the model for a fix, then return for approval

Two ways in: OAuth login, or **manual entry** (paste your instance URL and session ID), which needs **no Connected App** and no admin setup.

WHAT IT BUILDS TODAY

- **Flow types:** record-triggered (before or after save, before delete), scheduled, platform-event-triggered, autolaunched, screen, and orchestration.
- **Flow elements:** decisions, loops, get/create/update/delete records, subflows, actions, scheduled paths, pause, custom errors, screens.
- **Other metadata:** Apex classes and triggers, LWC, custom objects and fields, platform events, custom metadata, permission sets, prompt templates, Agentforce agents.
- **Preview:** Flows render as a diagram; LWCs get a live structural preview of the UI.
- **Customer portal tab:** public site, sign-up, My Account, chat.

THE REPORT: WHAT YOU HAND TO A REVIEWER

One self-contained HTML file per request (print it to PDF). For every piece it contains the **design** (diagram, field table or source), the model's **reason** for the choice, the **LWC preview**, and **how to test it**: for a record-triggered flow, a ready SOQL query for a record that satisfies the entry criteria; for a screen flow, the inputs Debug will ask for.

PRIVACY: USE OURS, OR BRING YOUR OWN KEY

Works out of the box: a server-side model allowance covers reasonable use, so you can start immediately with nothing to set up. For heavier use, or when your data terms require it, paste **your company's Anthropic API key (BYOK)**: usage, billing and data terms are then governed by your own Anthropic agreement. (Gemini and Ollama are also supported.) No account system either way.

What	Where it lives	Detail
Your API key (BYOK)	Your browser only	Saved in that browser's local storage and sent with each request so the server can call the model. Never written to disk or a database.
Salesforce token	Browser memory only	Held for the tab, not saved; gone on close or reload. Your org's metadata is fetched on demand and discarded.
Work in progress	Server memory	Stateless in the sense that matters: no database, no accounts, no history. A restart forgets everything.
Share link (optional)	Short-lived store	Only if you press Share: unguessable link plus 6-digit password, auto-deleted after 24 hours.

Hosted, your prompts pass through the server's memory on the way to Anthropic. For strict environments the same tool runs **self-hosted** (one Python package, or locally with the sf CLI), so traffic goes only from your machine to Anthropic and your org.

WHAT IT COSTS IN TOKENS

Task	Typical model cost*	Task	Typical model cost*
Object, field, small Apex class	about $0.01 to $0.03	Multi-piece plan (4 to 6 steps)	about $0.20 to $0.80
One Flow, incl. a repair round	about $0.05 to $0.30	Each follow-up "change it" request	about $0.02 to $0.15

*Estimates from list prices and prompt sizes; a live token and cost meter in the app shows actual spend per session, which is the source of truth.

Early build: free for fair use, no cost and no registration. Hosted on Heroku. Python-based; features are still being added. Human-in-the-loop by design: the model proposes, you decide.

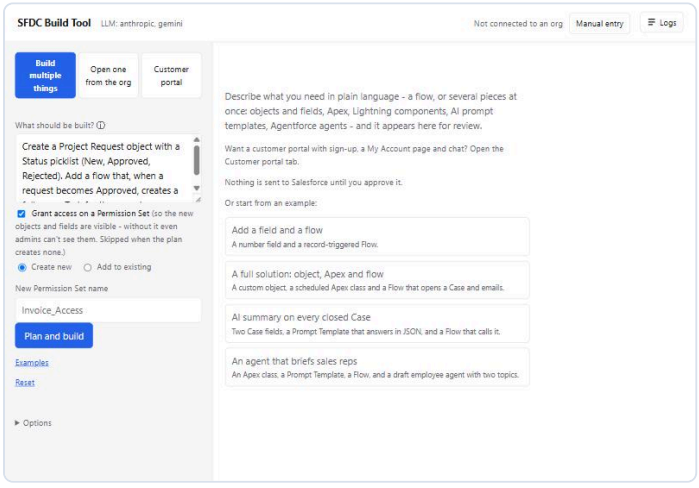

Quick start

From zero to a validated deploy in about 10 minutes. Written for a Salesforce admin; no coding needed.

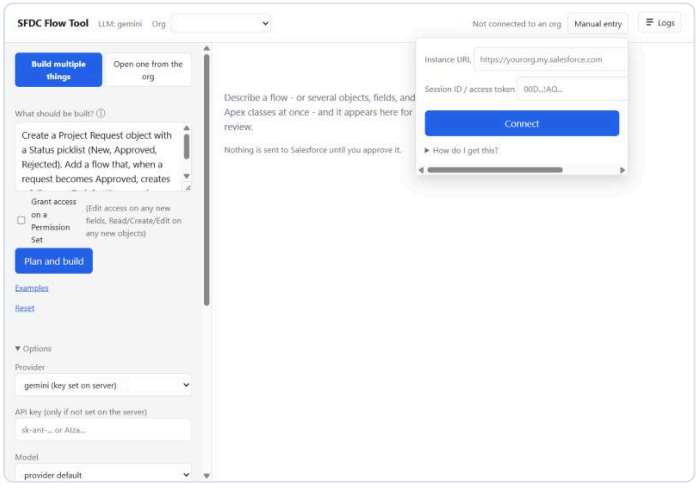

1. **Open it. There is nothing to set up.** Go to salesforce-debugtool.herokuapp.com/flow-tool. A model allowance for reasonable use is built in, so you can start immediately. Optional: under **Options**, paste your own Anthropic API key (BYOK) for heavier use or your own billing and data terms; it stays in your browser only. Leave Model on "provider default" and Effort on *medium*.
2. **Connect an org (optional, use a sandbox first).** Without it you can design and download everything; with it you can open existing metadata, validate and deploy. Use **Log in (Sandbox)** if shown, otherwise **Manual entry**: paste the instance URL and a session ID. Fastest ways to get the session ID: a Visualforce page containing `{!GETSESSIONID()}`, or `sf org display` / `sf org auth show-access-token`. It is held in the tab only.
3. **Pick a mode.** Build multiple things one request becomes an ordered plan: objects, fields, Apex, triggers, flows, LWC, platform events, prompt templates, Agentforce agents, deployed together in one transaction (a flow can use a field created in the same request). A single Flow or LWC is simply a one-step plan. Open one from the org an existing Flow, Apex class, trigger, LWC, prompt template, custom object or custom field: have it explained, then change it. An object opens as a plan, with a step per field. Customer portal builds an Experience Cloud site: public home page, self-registration, a My Account page and optional chat.
4. **Write the request like a spec.** Name the object and fields, the trigger ("when a Request is set to Approved"), the conditions, and the outcome. One process per request. The **Examples** button has ready specs, from a single field to full solutions and AI examples (a prompt template, a service agent, an employee agent), each saying what you get and what to prepare. **Use exact API names for anything that already exists** (e.g. `Account.Tier__c`): the tool does not read your org's schema while designing, so a loosely named field may be guessed wrongly and only fails at Validate.

   > *"Create a Project Request object with a Status picklist (New, Approved, Rejected). Add a flow that, when a request becomes Approved, creates a follow-up Task for the record owner."*

5. **Review, then refine.** Each step is a card. Flows show **Diagram, Explain, Documentation, Test** and **Flow XML**; objects show a field table; Apex shows the source; prompt templates show their text and answer keys; agents show their topics and actions; LWC adds a **Preview**. Not right? Type the change in **Change something** (or **Revise plan** to add or remove steps). Warnings sit above the diagram.
6. **Approve, Validate, Deploy. Approve** unlocks **Validate** (check-only against the org, nothing created), which unlocks **Deploy**. Flows deploy as **Draft** unless you tick *Deploy Active*. New objects and fields get access on a Permission Set. Agents deploy as drafts: an employee agent can be published and activated from its own step, a service agent (which asks for the Einstein Agent User it runs as) in Agentforce Builder. Any edit after approving requires approving again. The org's own error, if any, is fed back to the model and the fix returns for approval.
7. **Take it with you. Download report** (HTML: design, reasons, test guide), **Download package (.zip)** to deploy with sf CLI or Workbench, **Push to Git (PR)** to commit it to a new branch, or **Share this** for a 24-hour link plus password so a colleague can pick up the review.

Build multiple things: a plain-language request, or start from an example.

Manual entry: instance URL plus session ID, no Connected App.

GOOD TO KNOW

If you see	It means
Validate says a field or object is missing	The request named it loosely and the model guessed. Put the exact API name in the request and revise.
Flow refused when opening	It uses a construct the tool cannot represent exactly (it names it). Refused rather than redrawn wrongly, so nothing is lost on redeploy.
INVALID_SESSION_ID	The session ID expired or belongs to another org. Reconnect.
Apex fails only at Validate	Pre-checks are structural (braces, class name); the compile happens in the org, and the error comes back for a repair.
High demand / quota error	The model provider throttled. Retry, or pick another model in Options.

New flows are created with a **GC_** name prefix so they are easy to find. Start in a sandbox, review the Test tab's guide, then promote the package through your normal release path.
